

Carbon stocks and changes across a network of Atlantic Forest plots

Simone Vieira
(NEPAM/UNICAMP, Brazil)

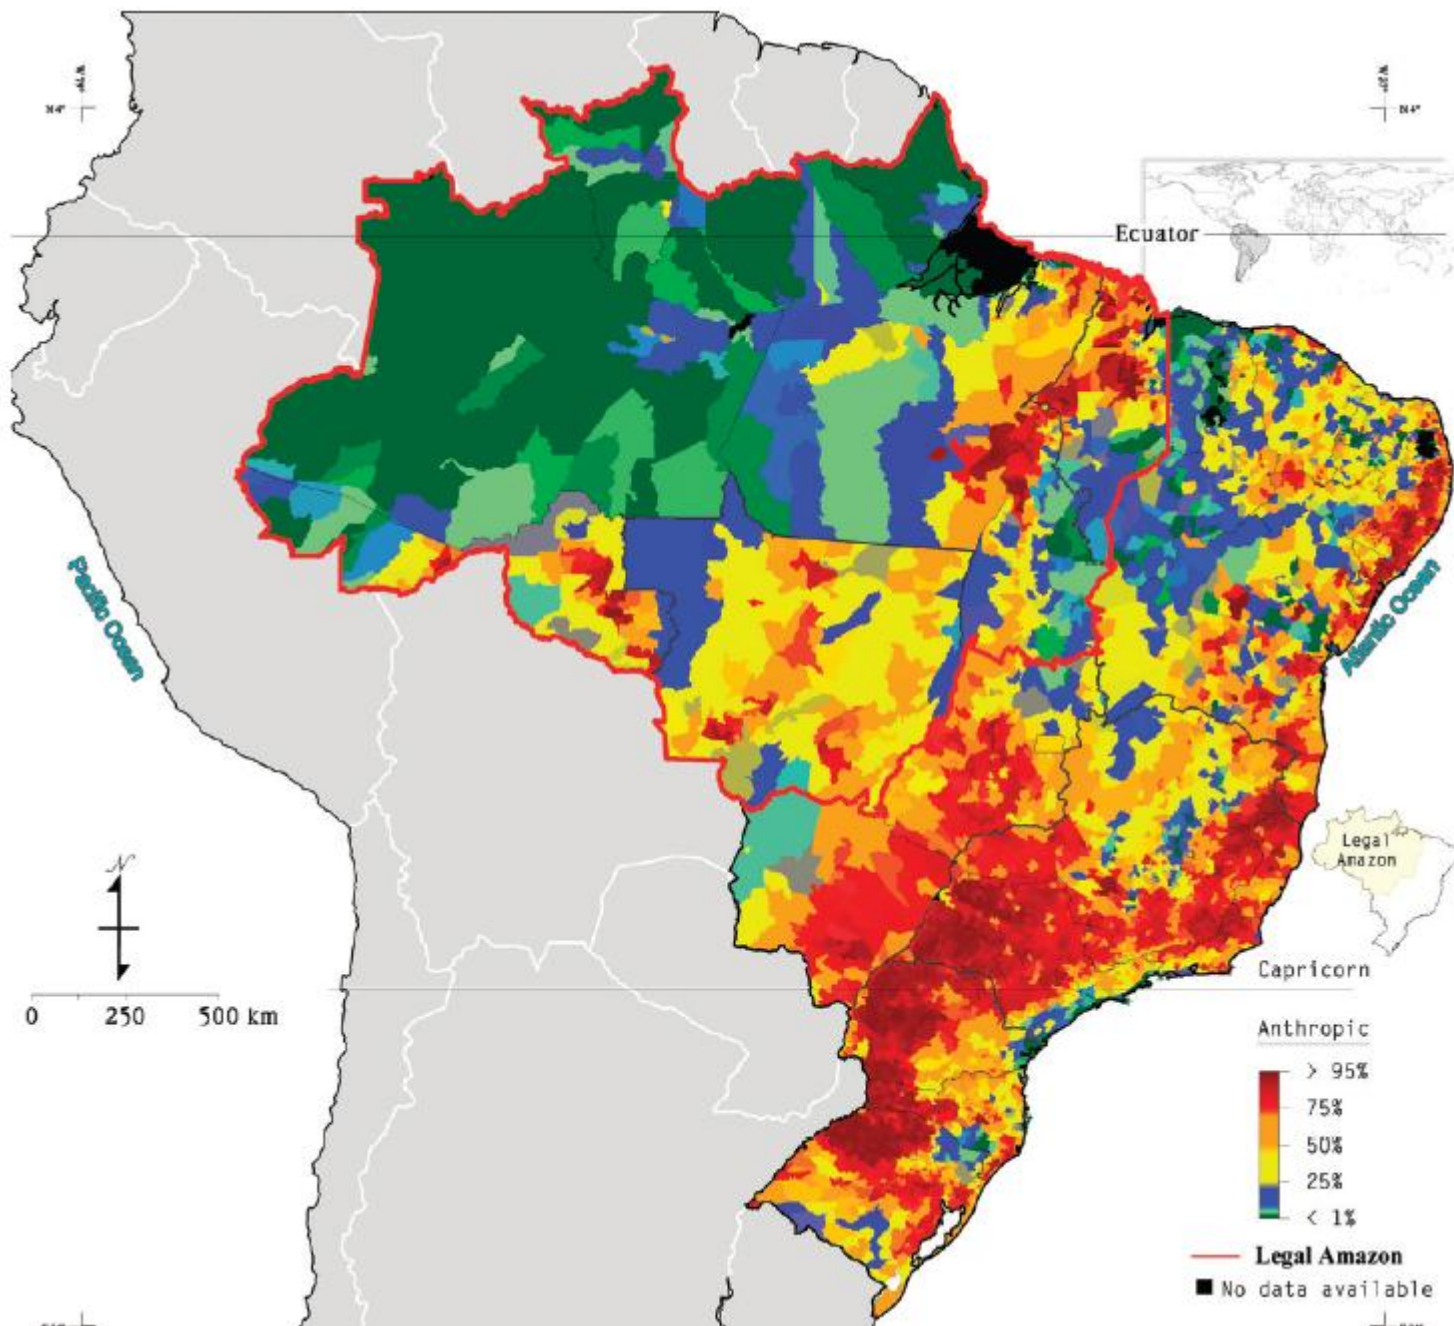

Forest cover South America

- the greatest concentration of tropical forests in the world
- Amazonian region
- Extra-Amazonian areas in the Pacific coast of Colombia and Ecuador and the Atlantic coast and Iguazu and Paraná River valleys

FAO

(2000)

The Atlantic Forest Cover before 1850 - ~1.5 million km²

The Atlantic Forest Cover before 1850 - ~1.5 million km²

*“...arvoredo que é tanto e tamanho e
tão basto e de tanta qualidade de
folhagem que não se pode calcular.”-*
Pero Vaz de Caminha (1500)

Actually is restricted to no mores than 12% of the original area

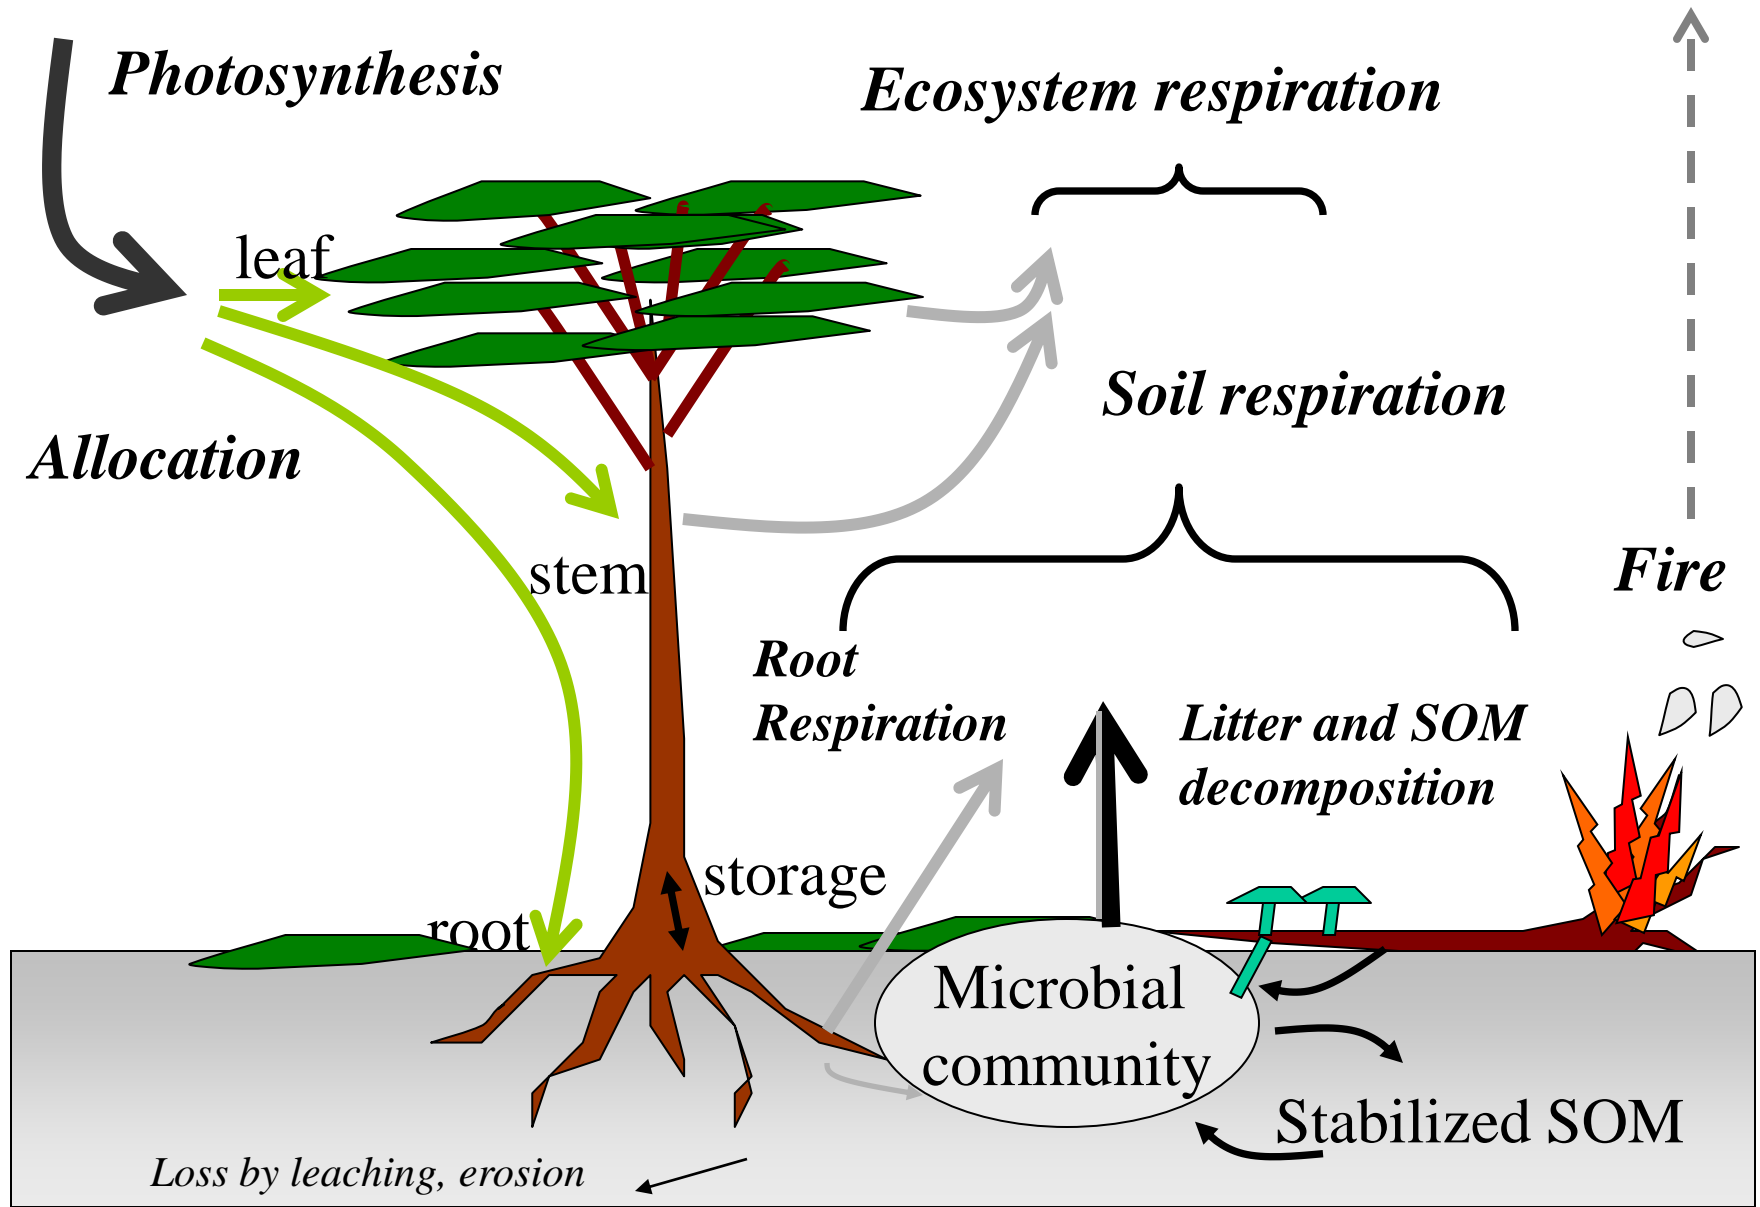

Photosynthesis → ← Respiration

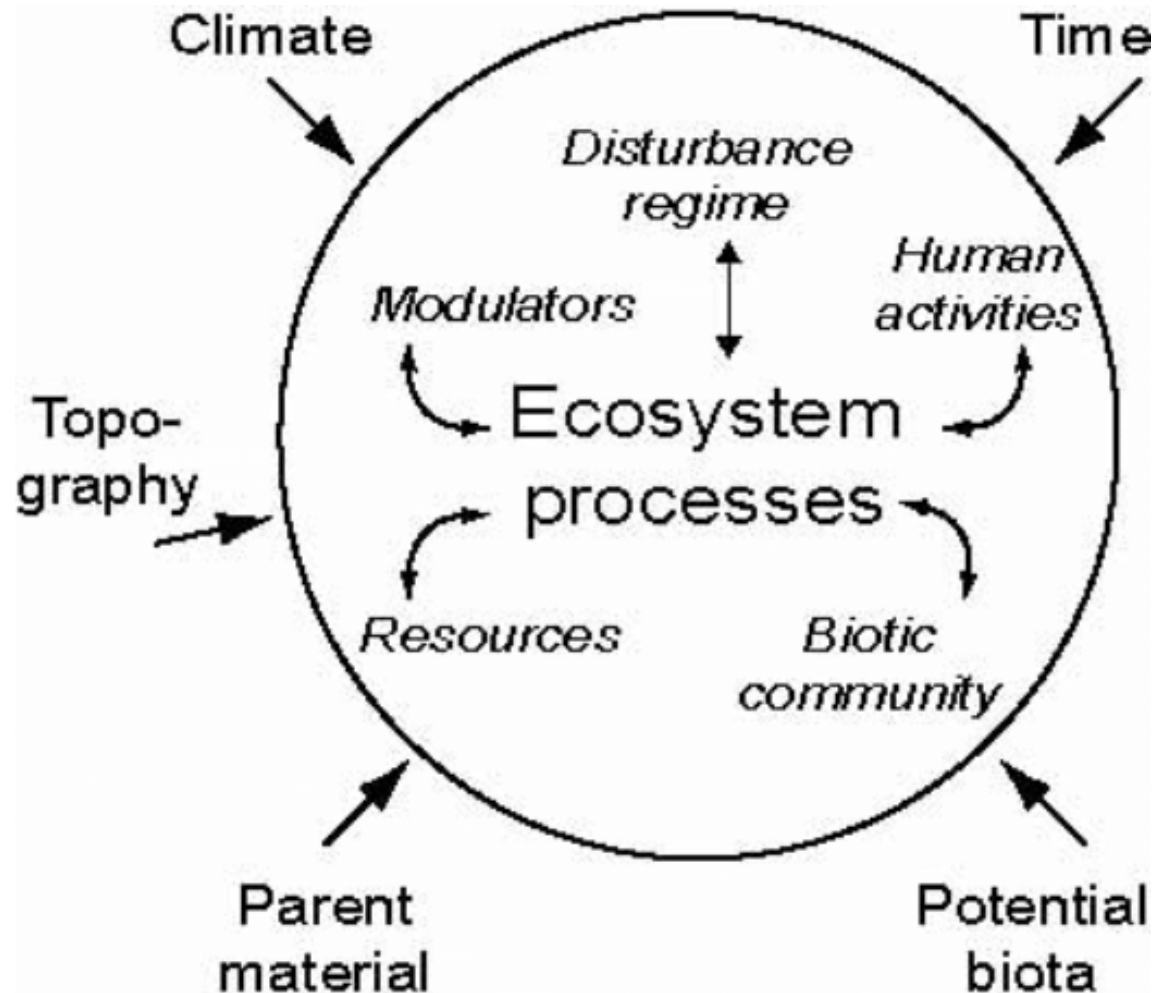

**If Photosynthesis exceeds Respiration,
Carbon dioxide will decrease and carbon is stored in
the ecosystem**

Carbon fixed by photosynthesis allocated to growth can store C for varying periods of time

Controls over ecosystem processes: state factors, interactive controls, and feedbacks

Research questions –

What is the capacity for these forests to store C?

Where could it be stored and for how long?

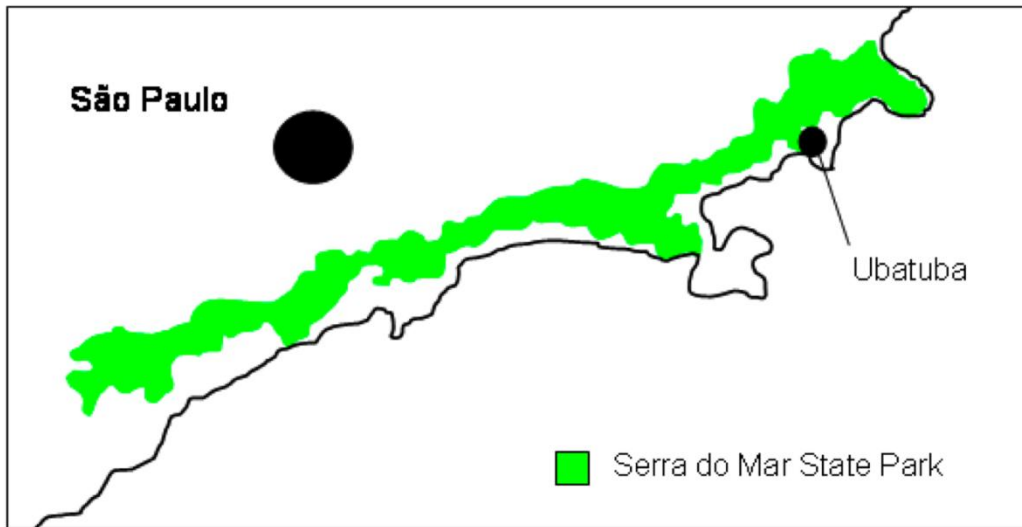

What is their potential to respond to global and local climate change?

Biota Project

- ✓ monitor forest structure and dynamics
- ✓ multi-temporal assessment of the floristic composition and species richness
- ✓ Ecosystem studies on N and C cycles

ATLANTIC FOREST

Tropical Moist Forest

Climate: tropical (3 months < 100mm)

Temperature: 22-24°C

Precipitation: 2500 mm

Soil C stocks and changes across a network of Atlantic Forest plots

Soil C stocks and changes across a network of Atlantic Forest plots

Conclusion

- The Tropical Atlantic Forest can be considered an important reservoir of carbon, which can store between 189-466 MgC ha⁻¹
- The global model predict there will have no change on total precipitaion
- Temperature may increase (~4°C –worst scenario)
- The increase of the temperature will direct affect total carbon stock in Atlantic forest, especially soil carbon stock
- By increasing temperature, carbon in “fast” and “slow” pools will also be affected

Thank you!

Table 1

Stand site and physical–chemical characterization of the surface soil layer (0–5 cm) sampled at four sites along the elevational gradient of tropical moist forest (Atlantic forest, Brazil). Mean values (\pm standard errors; $n = 32$). Adapted from Martins et al. (in review).

Site parameter	Forest type			
	<i>Restinga</i> (seasonally flooded forest)	Lowland	Submontane	Montane
Plot code	A	B, C, D, E	G, H, I, J	K, L, M, N
Plots (1 ha)	1	4	4	4
Elevation (m a.s.l.)	0–50	50–100	100–500	500–1200
Topography	Flat (0–10°)	Gentle (10–30°)	Steep (>30°)	Steep (>30°)
Soil type	Quartzipsamment	Inceptisols	Inceptisols	Inceptisols
Soil texture (%)	88.1% sandy	60.4% sandy	66.7% sandy	57.4% sandy
	6.1% clay	31.5% clay	16.4% clay	20.3% clay
Soil pH ^a	3.4	3.6	3.6	3.5
CEC (mmol _c kg ^{−1})	111.6	138.4	193.2	163.0
P (mg kg ^{−1})	11.5	17.6	12.9	21.2
