

Epidemiological genetics and phenotypes in sleep disorders resulting from malformations
Cytotoxic effects of sleep deprivation
Relationship between physical activity and sleep
Cardiovascular and metabolic alterations
Breathing disorders related to sleep, with an emphasis on autoimmune diseases and sleep disorders
Sleep, genital reflexes and hormones
Circadian rhythms
Sleep and cognition

Main Research Topics

Summary of Results to Date and Perspectives

The apnea-hypopnoea index is not enough to diagnose obstructive sleep apnea
There is a great individual variability in the stability of the apnea-hypopnoea index (AHI) from one night to another. Thus, for an adequate obstructive sleep apnea diagnosis, AHI should be used along with other clinical and polysomnographic parameters.

Development of an animal model of Periodic Leg Movement (PLM)
Considering our observation that paraplegic individuals present frequent periodic leg movement (PLM), we proposed an animal model of PLM based on the higher incidence of limb movements during non-REM sleep in spinal cord injured (SCI) rats. Our model demonstrated that these movements may be generated in the spinal medulla without involvement of cortical structures (Brain Res. 1017:32-8, 2004).

Mechanisms of paradoxical sleep deprivation-induced anemia
We have demonstrated that the amnesic effect of PSD in mice is also related to a concomitant antiangiogenic effect of PSD (Neurobiol. Learn. Mem. 82:90-4, 2004), is not related to modifications in GABAergic transmission, but is mediated by norepinephrine transmission (Psychopharmacology 176:115-22, 2004).

Mechanisms of sleep deprivation-induced facilitation of genital reflexes
The facilitatory effect of paradoxical sleep deprivation (PSD) on spontaneously genital reflexes in rats is associated with increased concentrations of progesterone and is dramatically potentiated by cocaine administration (J. Neuroendocrinol. 16:154-9, 2004).

Anestrous in paradoxical sleep deprived female
Sleep deprivation presents distinct, long-lasting effects on estrous cycle (leading to a prolonged period of anestrus), and may modulate the ovarian hormone release through alterations in hormonal-neurochemical mechanisms (Horm. Behav. 49:633-40, 2006).

The hyperfagia/weight loss paradox during sleep deprivation
The hyperfagia/weight loss paradox in sleep deprived rats results from difficulties in obtaining food to reach energetic needs especially during the first day of sleep deprivation, after which the animals adapt to the procedure (Sleep, 29:1233-8, 2006).

A double-blind, placebo-controlled, crossover study of sildenafil in obstructive sleep apnea (OSA)
Sildenafil taken close to bedtime significantly worsens respiratory and oxygen saturation (SaO₂) variables during sleep in men, when compared to placebo. Sildenafil taken close to bedtime significantly worsens respiratory and oxygen saturation (SaO₂) variables during sleep in men, when compared to placebo. Sildenafil taken close to bedtime significantly worsens respiratory and oxygen saturation (SaO₂) variables during sleep in men, when compared to placebo. Sildenafil taken close to bedtime significantly worsens respiratory and oxygen saturation (SaO₂) variables during sleep in men, when compared to placebo. Sildenafil taken close to bedtime significantly worsens respiratory and oxygen saturation (SaO₂) variables during sleep in men, when compared to placebo.

Acupuncture is an effective treatment for moderate obstructive sleep apnea syndrome
Ten weekly sessions of acupuncture significantly improved the respiratory events of patients presenting with moderate OSA in comparison to treatment with the sham procedure (needle insertion in non-acupoints) and to non-treated controls. Acupuncture also improved quality of life and decreased subjective sleepiness (Sleep Med. 8:43-50, 2007).

Worsening of sleep complaints: an epidemiological study
We compared the prevalence of complaints of insomnia, excessive diurnal sleepiness, parasomnias, and sleep habits of the adult population in the city of São Paulo, Brazil, estimated in surveys carried out in 1987 and 1995 (1000 adult each, Braz. J. Med. Biol. Res. 40:1505-15, 2007). Difficulty in maintaining sleep, initiating sleep and early morning awakening significantly increased throughout time, mainly in women. Besides sleeping slightly less, interviewees went to bed and woke up later in 1995. These major changes over a little less than a decade’s time should be considered as an important public health issue.

Donepezil decreases apnea/hypopnoea in Alzheimer’s patients
We found that donepezil improves apnea/hypopnoea index and oxygen saturation during sleep in Alzheimer disease patients with obstructive sleep apnea, despite REM sleep increase. This was the first controlled trial to show this magnitude of improvement of respiratory parameters, during sleep, with one drug (Chest. 133:677–683, 2008).

Gene expression changes after sleep deprivation (unpublished data)
Paradoxical sleep deprivation promotes a number of behavioral, physiological, as well as cellular functioning alterations, including gene expression in specific brain regions. A total of 55 genes were found to be differently expressed in rats after 96 hours of sleep deprivation. Interestingly, after 24 hours of sleep recovery (rebound), approximately 50% (n=25) of the PSD genes had their expression returned to control levels. Also, 200 transcripts, such as A2B receptor, Insulin receptor substrate2, Corticotropin releasing hormone, and Homer1, were specifically altered when compared to sleep deprivation condition. These data raise a number of potential candidates for the molecular basis of homeostatic mechanism of sleep regulation.
